Object Oriented Modeling and Design Object-Oriented Analysis, The Domain Model Unlike other engineers, software engineers work in different areas, with various needs and business rules. For example, they develop software for airline companies, banks, and embedded systems like car engines. Therefore, it is not sufficient to know about the software domain; a software engineer also needs to know about the problem domain. A domain model illustrates concepts in a problem domain (real world). UML class diagrams are used to present domain models. It may show three items: 1. Domain objects or conceptual classes 2. Associations between conceptual classes 3. Attributes of conceptual classes Benefits of the domain model: 1. It helps us to understand the (real-world) system. 2. It acts as a source when we define software classes at the design level.

Object Oriented Modeling and Design

## How to Create the Domain Model?

- 1. Find the conceptual classes.
- 2. Add associations and attributes.
- 3. Draw them as classes in a UML class diagram.

## How to Find Conceptual Classes?

Three strategies to find conceptual classes:

1. Reuse or modify existing models.

If there is an existing model from a previous project, it can be modified. There are also published domain models for many common domains, such as inventory, finance, health, etc.

2. Use a category list.

You can define conceptual classes in your application domain using the list containing many common categories.

3. Identify noun phrases in the use cases.

Object Oriented Modeling and Design			
Finding Conceptual Classes with Noun Phrase	Identifica	tion	
Identify the nouns and noun phrases in textual des cases), and consider them as candidate conceptual	scriptions o classes or	ot a domain (use attributes.	
Main Success Scenario (or Basic Flow):			
1. Customer arrives at a POS checkout with goods and/	or <u>services</u> t	o purchase.	
<ol><li><u>Cashier</u> starts a new <u>sale</u>.</li></ol>			
<ol><li>Cashier enters <u>item identifier</u>.</li></ol>			
4. System records sale line item and presents item desc	ription, price	<u>e</u> , and running <u>total</u>	. Price
calculated from a set of price rules.			
Cashier repeats steps 3-4 until indicates done.			
5. System presents total with <b>taxes</b> calculated.			
6. Cashier tells Customer the total, and asks for <b>payment</b> .			
7. Customer pays and System nandles payment.			
8. System logs completed sale and sends sale and payme	nt informatio	n to the external	
inventory)	na <u>inventor</u> y	system (to update	
9 System presents <b>receipt</b>			
10.Customer leaves with receipt and goods (if any).			
Extensions:			
7a. Paying by cash:			
1. Cashier enters the cash amount tendered.			
2. System presents the <b>balance due</b> .

Object Oriented Modeling and Design			
Eliminating unnecessary noun phrases			
All noun phrases in use cases do not represent conceptual classes.			
The following noun phrases should be eliminated:			
1. Different noun phrases may represent the same conceptual class.			
For example, the customer and user are redundant. Use "customer" because it is more descriptive.			
<ol><li>Some noun phrases may refer to conceptual classes that are ignored in this iteration (for example, "accounting" and "commissions").</li></ol>			
<ol> <li>Some noun phrases may refer to attributes. Attributes should be basic data types such as numbers and text.</li> </ol>			
This method can be used in combination with the "Conceptual Class Category List" technique.

Object Oriented Modeling and Design			
The Mapmaker Approach			
A domain model is a kind of map of concepts or things in an application domain.			
Make a domain model in the spirit of how a cartographer or mapmaker works:			
<ul> <li>Use the existing names in the territory.</li> </ul>			
Mapmakers do not change the names of cities on a map.			
Use the vocabulary of the domain when naming conceptual classes and attributes.			
<ul> <li>Exclude irrelevant features.</li> </ul>			
For example, on a physical map, the borders of cities are not shown.			
Do not put classes or attributes on the model if they do not have any obvious noteworthy role—for example, the keyboard and the age of the cashier.			
<ul> <li>Do not add things that are not there.</li> </ul>			
A mapmaker does not show things that are not there, such as a mountain			
that does not exist.			
Similarly, the domain model should exclude things <i>not</i> in the problem domain under consideration—for example, the owner of the store.			
https://www.akademi.itu.edu.tr/en/buzluca ©2012 - 2022 Feza BUZLUCA 3.8			

Object Oriented Modeling and Design			
Example: Conceptual classes of NextGen POS syste	em for the firs iteration		
Store Register Cashier Item Sale Sales Line Item	- Register - Item - Store - Sale - Sales Line Item		
Payment Ledger Customer	- Cashier - Customer		
Product Specification Catalog	<ul> <li>Ledger</li> <li>Payment</li> <li>Product Catalog (next slide)</li> <li>Product Specification (next slide)</li> </ul>		
The class "Ledger" can be discovered in this step because of the statement in the use case: "System logs completed sale."			
If we did not think of a Ledger during analysis, we would discover it when we designed the operation about logging a completed sale (slide 5.11).			
There is no such thing as a "correct" list. However, by following the identification strategies, different modelers will produce similar lists.

Object Oriented Modeling and Design			
Need for description (specification) classes			
In some systems, <b>description</b> (or <b>specification</b> ) cla domain model, even though they are not mentioned	isses shoul in the use	ld take place in t e cases.	the
Example:			
Assume that information about physical items in a such as serial number and price.	store is w	ritten on these	items,
It seems logical because these data are attributes	s of these	items.	
However, some data may be lost when all items are	e sold out.		
Another problem arises when we want to change properties, such as the price of products. In such a case, we must update all items (objects).			
In such systems, it is necessary to keep these date classes.	a in separa	ate description	
Description objects are stored in a <b>catalog</b> .

Object Oriented Modeling and Design			
Operation Contracts			
Use cases and domain models are usually sufficient to understand the requirements of the stakeholders and the expected features of the system under discussion.			
Now, it is possible to start with design.			
However, for complex system operations (statements in a use case), a more detailed or precise description of system behavior may be necessary.			
An <b>operation contract</b> is written for each <b>complex system operation</b> (statement) in the use cases to describe its details.			
Examples of system operations: "Make a new sale", "Enter Item ID", and "End sale".			
An <b>operation contract</b> describes changes in the state of objects in the domain model when the related operation (e.g., Make a new sale) has finished.			
In other words, it describes what happened to the objects in the system during the execution of the related operation (e.g., Make a new sale).			
Remember, we are still in the real world (application domain), not talking about software objects or attributes.			
Operation contracts help us to find the <b>responsibilities</b> of the system.

Object Oriented Modeling and Design

## Format of an operation contract

Contract number and name

**Operation:** Name and parameters (signature)

Reference: The related use case

Preconditions: What must be true to run this operation.

Postconditions: Changes in the state of objects in the domain model.

The **postconditions** describe changes in the state of objects in the domain model when the related operation has finished.

Postconditions are divided into three categories:

- 1. Instance (object) creation and deletion.
- 2. Attribute change of value.
- 3. Associations (links, connections) formed and broken.

Remember: we are looking for the answer to "what".

How these operations are performed is an issue that we deal with in the design step.

Postconditions give us the **responsibilities** we must assign to the objects in the design.

3.19

Object Oriented Modeling and Design			
How to write postconditions?			
Postconditions <u>are not actions</u> to be performed during the operation;			
instead, they are <u>observations about the domain model objects</u> that are true when the operation has finished.			
What happened to the objects in the system (real world) after the operation?			
We are still interested in <b>what</b> happened, <u>not</u> how it is performed.			
How these contracts are realized is the issue of the design level.			
Express postconditions in the <b>past tense</b> to emphasize that they are observations about state changes.			
Analogy: The Stage of a Theater (Taken from Larman)			
The system and its objects are presented on a theatre stage.			
1. Before the operation, take a picture of the stage.			
<ol><li>Close the curtains on the stage and apply the system operation (background noise of clanging, screams, and screeches).</li></ol>			
3. Open the curtains and take a second picture.			
<ol> <li>Compare the before and after pictures and express as postconditions the changes in the state of the stage (A SalesLineItem was created).</li> </ol>			
Now we know the changes, but not how (by whom) they are made.			
https://www.akademi.itu.edu.tr/en/buzluca ©2012 - 2022 Feza BUZLUCA 3.21			

Object Oriented Modeling and Design			
Example: enterItem			
The statement in the use case "Cashie	er enters item identifier." seems to be simple.		
However, associated operations can be	e complicated.		
Therefore we write a contract for thi	s operation.		
0			
L I I	Contract CO2: enterItem		
: Cashier :Svstem	Operation:		
makeNewSale()	enterItem(itemID: ItemID, quantity: integer) <b>Reference:</b> Use Cases: Process Sale		
	<b>PreCond</b> : There is a sale underway		
loop [more items]			
enterItem(itemID, quantity)	- A SalesLineItem instance sli was created		
description, total	(instance creation)		
	- sli was associated with the current Sale		
	(association formed)		
 	- sli.quantity became quantity (attribute		
All objects and classes (for example, sli,	modification)		
Sale, Product Spec.) mentioned in contract	- sli was associated with a Product Spec.		
We are not writing the program.	based on itemib match (association formed)
